

**5.1-3****a**

wrong! vertex  $v$  is on a circle, but  $v$  is a cut-vertex. Because each path from  $u$  to  $k$  will pass  $v$

**b**

wrong! vertex  $u$  is not on any circle, but  $u$  is not a vertex obviously

**c**

wrong!

As the graph in section b, vertex  $u, v, s$  construct a tree of order 3

but the number of cut-vertex is 1, only  $s$ . and the number of end-vertex is 2.

**d**

wrong

As the graph in section b, there are two edges  $u - s, s - v$ , but there is only one cut-vertex.

**5.1-4**

if  $v$  is a cut-vertex of the complement  $\bar{G}$  of  $G$  then there are two vertices  $u, s$ , each path between them will pass  $v$ ,

case 1:

if  $u, s$  are in different components in  $G$ , then there will be an edge between  $u, s$ , so this case will not be true.

case 2:

if  $u, s$  are in the same component in  $G$ , then there we can use a vertex  $m$  in another component, so we can find edges between  $u, m, s, m$ , so there is a path between  $u, s$  not passing  $v$  so this case does not occur.

because there are only these two cases, so we know  $v$  is not a *cutvertex* in graph  $\bar{G}$

As the graph in section b, there are two edges  $u - s, s - v$ , but there is only one cut-vertex.

**5.1-6**

1.

if  $G$  is 3-regular graph with a cut-vertex, so it doesn't matter if we assume there are two components

in  $G-v$ , so we know there are two edges between vertex  $v$  and Component  $G_1$ , there is a edge between vertex and component  $G_2$ , so this edge lies on no circle. so this edge is a bridge 2.

if  $G$  is 3-regular graph with a bride, from thorem 5.1, since  $degv = 3$ , so  $v$  is a cut-vertex

## 5.2-10

if graph  $G$  of size at least 2 is nonseparable, so let  $edge(u,v)$ , and  $edge(v,s)$  be two adjacent edges, if they are not on a common edge, so if we remove vertex  $v$ , there will be no path between  $u,s$ . so this conflict with the graph is not noseparable graph, so any adjacent edges will lie on common circle

if any two adjacent edges of  $G$  lie on a common cycle of  $G$ . so we guess if exists two vertex  $u,v$ , each path between them will pass  $s$ , so we let the path be  $u \rightarrow s_1 \rightarrow s \rightarrow s_2$ , so we know  $edge(s_1,s), edge(s_2,s)$  are on a circle, so there is a path between  $(u,v)$ , not pass  $s$ , but go through the circle exclude  $s$ , so the graph is noseparable.

## 5.2-11

we assume the graph is not noseparable, so there is a cut-vertex  $v$ , so we may assume there are two components in graph  $G-v$ , they are  $G_1, G_2$ , so the maximum of the smaller order of two components is  $\lfloor (n-1)/2 \rfloor$  the max degree of the vertex in this component is  $\lfloor (n-1)/2 \rfloor$  (it has edge between each vertex in its component and vertex  $v$ ), but we know  $deg \text{ vertex} \geq n/2$ , so it conflicts. and assumption is wrong. (if there are more than two components, it is still wrong in this way)

## 5.2-14

### 0.0.1 a

because  $G_1$  is a component, so we only need to show that vertex  $v$  is connected with some vertex in  $V(G_1)$ , because  $v$  is cut-vertex, there must be some vertex in  $V(G_1)$  are adjacent to  $v$  so  $G(V(G_1) + v)$  is a connected graph

### b

as the graph show, if the  $V(G_1)$  is  $w,k,j$ , and the cut-vertex is  $v$ , so the graph that  $v,w,k,j$  construct

is not noseparable graph

## 5.2-15

we choose a edge from  $G$ , so we can proof that the block found by (1) is same as the block found by (2) which they all contain  $edge(u,v)$

if  $block_2$  contain a edge  $(s,w)$  called  $e$ , so  $s,w,u,v$  is on common circle, so because each two vertex in  $(s,w,v,u)$  are on a common circle so  $s,w,u,v$  also construct a noseparable graph, this said each vertex in  $block_2$ , it will lie on  $block_1$

then as we know, each two vertices in  $block_1$  are lie on the same circle, each edge  $(k,m)$  in  $block_1$  is on a circle, then we want to show, that this edge is on the same circle with  $edge(u,v)$ , so we assume,

edge( $k,m$ ) and edge( $u,v$ ) is not on the same circle, then there are at least two circle in the graph and they are connected only by a vertex, so if we remove this vertex ,this graph is disconnected, so it conflicts, and the any edge in  $block_1$  is on the same circle as edge( $u,v$ ) so each vertex in  $block_1$  is in the  $block_2$   
so  $block_1$  and  $block_2$  are same

**5.3-20****a** $k=2$ 

if the graph is not 2-connected, so it is 1-connected ,so vertex-cut's size is 1

**b**

if the graph is not 2-edge-connected,since it is connected, so it is 1-edge-connected ,so vertex-cut's size is 1

**5.3-22****a**

if  $G - e$  is  $(k-2)$ -connected, so let the vertex-cut be  $V$ ; if  $e$  is incident to  $V$ ,so  $G-V$  and  $(G-e)-V$  is same,so  $G$  is  $(k-1)$ -connected, contradiction. if  $e$  is not incident to  $V$  ,so science  $G-V$  is connected  $(G-e)-v$  is disconnected, so we can remove a vertex incident to  $e$ , so  $G$  is not connected so  $G$  is  $(k-1)$ -connected, contradiction.

**b**

if  $G - e$  is  $(k - 2)$ -edge-connected, then  $G$  is  $(k-1)$ -edge-connected, obvious wrong

**5.3-30****6.1-4****a**

**b****c****d****d****6.1-5****6.1.6**

the graph is  $(2n+1)$  regular graph and  
 if graph is  $2m$ -order, and  $\bar{G}$  is connected, bar is even-regular graph if graph is  $(2m+1)$ -order, it can not  
 be a even-regulr graph ,so it must be a Eulerian

**6.2.13****a**

as the graph shows, if we remove vertex  $s2$  and  $s7$  thne left 4 componets and  $4 > 2$ , so from theorem

6.5, this graph is not Hamiltonian

**b**

each vertex's degree is 3, so it is not Eulerian.

**c****d****6.2.16****a**

let  $G$  be  $r$ -regular,  $\bar{G}$  be  $s$ -regualr, because order of  $G$  is even, so  $r+s$  is a odd number, sience neither  $r$  or  $s$  is 0, so there is one and only one in  $G$  and  $\bar{G}$ ], which is a even-regular graph, so either  $G$  or  $\bar{G}$  is Eulerian.

b

Corollary 6.7: Let  $G$  be a graph of order  $n \geq 3$ . If  $\deg v \geq n/2$  for each vertex  $v$  of  $G$ , then  $G$  is Hamiltonian.

first when order is less than 3, it conflicts with that both  $G$  and  $\bar{G}$  is connected

then we let the order of  $G$  is  $2n$ .

so the let  $G$  be a  $r$ -regular, and  $\bar{G}$  be a  $k$  regular. so  $r+k=2n-1$ .

if neither  $r$  or  $k$  is  $n$ , neither  $G$  and  $\bar{G}$  will be Hamiltonian, so  $r < n, k < n$ , so  $r + k \leq 2n - 2$  so this is a contradiction. so also we can proof not both  $r$  and  $k$  can not be larger than  $n$ , so either  $G$  or is Hamiltonian.

### 6.2.21

we can add a new vertex  $s$  to  $G$ , and add a edge between  $s$  and each vertex in  $G$ . so we get a new graph,  $G_2$ , and every two non-adjacent vertices  $x, y$  in  $G$  their degree's sum is greater than  $n$ ; so from theorem 6.6 we know  $G_2$  is Hamiltonian. so we remove the vertex  $s$  from the circle, and we get a Hamiltonian path.
